# 1 Blockbusting in the 21st Century?: Minority Move-ins and Neighborhood Home Value Appreciation

#### 1.1 Introduction

I am using the Fannie Mae (FNMA) & Freddie Mac (FHLMC) data to analyze the demographics of move-ins on a census-tract level. This, with the census-level demographic data (ACS), can provide an estimate of a quantity of minority "move-ins". I am seeing the extent to which this has an effect on the appreciation in home values (Zillow ZHVI)

My **y-variable** is census-tract property value appreciation. My main **explanatory variables** are minority move-ins and previous neighborhood demographics. I will be controlling for income.

#### 1.2 Data Loading

We start by loading libraries. For dataframes we are using pandas, for plots we are using pyplot from matplotlib.

```
[1]: import pandas as pd import matplotlib.pyplot as plt import numpy as np
```

Because the data is in .txt format, with no column headers, and is in many different files for different years and loan types, some light data cleaning is required. To begin, we set up short titles for each column based on the data dictionary provided, and create a list of columns we do not need.

```
[2]: def read_columns_from_txt(filename):
    data = {}
    with open(filename, "r") as f:
        for line in f:
            key, value = line.split("=", 1)
            data[key.strip()] = eval(value.strip())
    return data

columns_data = read_columns_from_txt("data/columns.txt")
    cols = columns_data["cols"]
    cols_pre2018 = columns_data["cols_pre2018"]
    dropcols = columns_data["dropcols"]
    dropcols_pre2018 = columns_data["dropcols_pre2018"]
```

```
cols_2013 = columns_data["cols_2013"]
```

We next must load our data using these columns. I created a load\_loans method to make it easier to modify the years we load. For this project, we are focusing on some of the earliest base years possible. In the future, I am interested in looking at moving base years.

```
[3]: def load loans(years):
         loans list = []
         for year in years:
             if year >= 2018: # The data format changes in 2018
                 files = [f"data/sf/fhlmc_sf{year}c_loans.txt", f"data/sf/

¬fnma_sf{year}c_loans.txt"]
                 loans_year = pd.concat(
                     [pd.read_csv(file, sep=r"\s+", header=None, names=cols).

¬drop(columns=dropcols) for file in files],
                     ignore_index=True
             else:
                 files = [f"data/sf/fhlmc_sf{year}c_loans.txt", f"data/sf/

¬fnma_sf{year}c_loans.txt"]
                 loans_year = pd.concat(
                     [pd.read_csv(file, sep=r"\s+", header=None, names=cols_2013).
      ⇔drop(columns=dropcols pre2018) for file in files],
                     ignore_index=True
             loans_year["year"] = year
             loans_list.append(loans_year)
             print(f"Processed {year}", end=" ")
         return pd.concat(loans_list, ignore_index=True)
```

[4]: loans = load\_loans([2010, 2011, 2012]) # Please forgive the print statement!\_\_

The full data can take upwards of 20 mins to load.

#### Processed 2010 Processed 2011 Processed 2012

Next, we analyze each loan to determine how many "minority move-ins" it corresponds to.

Finally, we add a column with the full census tract code for future merging

```
[6]: loans['longtract'] = loans['state_fips'].astype(str).str.zfill(2) +

→loans['county_fips'].astype(str).str.zfill(3) + loans['census_tract'].

→astype(str).str.zfill(6)
```

Next, we load in the census data to give us information about neighborhood demographics

Next, we load in the Zillow data for information about home prices

```
[8]: zhvi = pd.read_csv('data/zhvi/Zip_zhvi_uc_sfrcondo_tier_0.33_0.67_sm_sa_month_

\(\disp(1).csv'\)
```

The Zillow data is based on zip-code, but all our other data is based on census tract. As a result, we use a Crosswalk File from HUD.

```
[9]: crosswalk = pd.read_excel('data/census/ZIP_TRACT_122024.xlsx')
```

Next, we merge the loan data into our crosswalk. We aggregate on each census tract.

Now that we have loan data, we merge with our Census data.

C:\Users\emers\AppData\Local\Temp\ipykernel\_5900\2146552024.py:5: UserWarning:
Boolean Series key will be reindexed to match DataFrame index.
 quite\_white\_hmmi = quite\_white[((merged\_data['minority\_move\_ins']\* 1000) /
merged\_data['total\_pop'] > 2)] # "high minority move in" = more than 2 per
thousand

Now we merge Zillow data

We have now, finally loaded our data. We have our quantity of minority move-ins, previous demographic makeup of the neighborhood, previous home values, and home values after a few years.

#### 1.3 Summary Statistics

In our filtered\_data table, we have information about our explanatory variables (demographics), our independent variables (initial property value), and our outcome variable (final property value)

```
[62]: final_value_summary = data_table[['value_change', 'avg_value_2023']].describe().
      →round(1)
     final_value_summary.columns = ['Value Change', 'Average Value (2023)']
     final_value_summary.index = ['Count', 'Mean', 'Standard Deviation', 'Minimum', |
      final value summary.loc['Range'] = final value summary.loc['Maximum'] - |

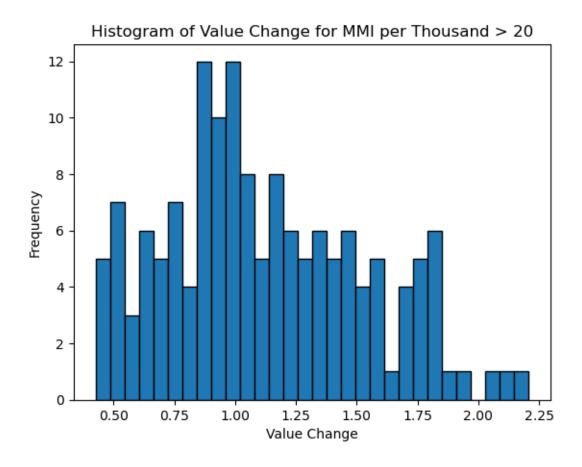

¬final value summary.loc['Minimum']
     # Styling
     styled_summary = final_value_summary.style.set_caption("Final Home Value_
      ⇔Summary Statistics").format("{:.2f}")
     styled_summary.set_table_attributes('style="width: 30%; margin: auto;"')
     styled_summary.set_table_styles([
         {
             'selector': 'th',
             'props': [('font-size', '14px'), ('background-color', '#f2f2f2')]
         }
     ])
     styled_summary
```

[62]: <pandas.io.formats.style.Styler at 0x21704234500>

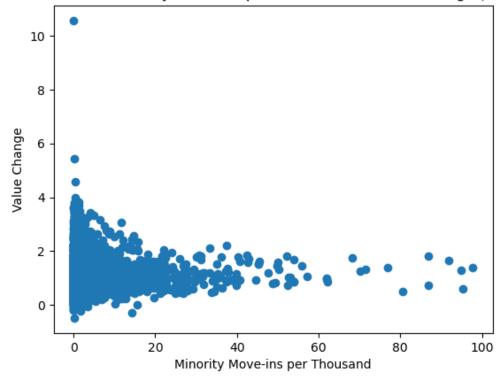

## 1.4 Plots & Figures

```
[]: # Filter the data where mmi_per_thousand is greater than 20
filtered_data_high_mmi = filtered_data[filtered_data['mmi_per_thousand'] > 20]

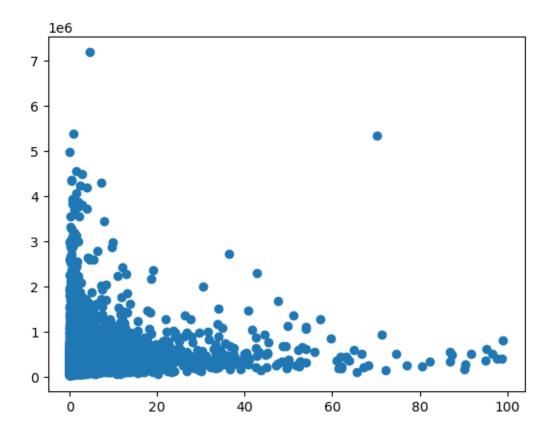

# Plot the histogram of value_change
plt.hist(filtered_data_high_mmi['value_change'], bins=30, edgecolor='black')
plt.xlabel('Value Change')
plt.ylabel('Frequency')
plt.title('Histogram of Value Change for MMI per Thousand > 20')
plt.show()
```

## Scatter Plot of Minority Move-ins per Thousand vs Value Change (Filtered)

```
[]: filtered_data = data_table[(data_table['mmi_per_thousand'].abs() < 100)]
plt.scatter(filtered_data['mmi_per_thousand'], filtered_data['avg_value_2023'])
plt.show()
```

```
[]: filtered_data = data_table[(data_table['mmi_per_thousand'].abs() < 100)]
   plt.scatter(filtered_data['mmi_per_thousand'], filtered_data['avg_value_2012'])
   plt.xlabel('MMI per Thousand')
   plt.ylabel('Average Value (2012)')
   plt.title('Scatter Plot of MMI vs Average Value (2012)')
   plt.tight_layout()
   plt.show()</pre>
```

### 1.5 Conclusion
